Each database management system (DBMS) conforms to a logical data model, that is, network, hierarchic, or relational. If a relational DBMS is chosen for the implementation, the conceptual schema is mapped to a relational schema, or relational database schema. Various frameworks also exist for information system architecture.

A relational database is a type of database that stores and provides access to data points that are related to one another. Relational databases are based on the relational model, an intuitive, straightforward way of representing data in tables. In a relational database, each row in the table is a record with a unique ID called the key.

## **What Is a Relational Database | Oracle**

The relational model (RM) for database management is an approach to managing data using a structure and language consistent with first-order predicate logic, first described in 1969 by English computer scientist Edgar F. Codd, where all data is represented in terms of tuples, grouped into relations. A database organized in terms of the relational model is a relational database.

Even at the lower level of the relational data model, E.F. Codd, the founder of the relational model, argues that "domains are the glue that holds a relational database together" (Codd 1990). The object types in ORM diagrams are the semantic domains, so the connectedness of a model is transparent.

In relational design, the focus and effort is around describing the entity and its relation with other entities; the queries and indexes are designed later. With a relational database you normalize your schema, which eliminates redundant data and makes storage efficient. Then queries with joins bring the data back together again.
